Problem Description

null

Solution

After the factory-configured AP is started, without registering to the AC, enter through the configuration port and run the command:

```
[H3C]display interface vlan 1
```

If the address is displayed as 192.168.0.50, this AP is Fat AP, if there is no address, it is a thin AP.

In another way, in the user view, use the "dir" command to view the startup version. If the underscore is followed by fit, it is a fit AP, and if it is fat, it is a fat AP.
